For example, a circuit board may include layers of circuitry, an insulating material to support the circuitry and to electrically isolate the circuitry, a ground plane, and a protective layer. The insulating material may comprise one or more polymeric materials including, for example, polyester. The grounding of electrical circuits can be quite important. For example, in an aircraft, electrical circuits such as circuit board grounding is important so that the electrical circuits do not electrically affect the aircrafts electrical components and systems, such as the aircraft engines. Due to the importance of grounding electrical circuits, special circuit board grounding systems have been developed. Prior art circuit board grounding systems have been used in aircraft in which a number of electrical connections are made to the aircraft aircraft ground. In the prior art aircraft grounding systems, electrical components such as resistors and capacitors are soldered directly to electrical connectors such as a ring or sleeve. The ring or sleeve is bonded to a ground plane on the circuit board and is placed in contact with the aircraft ground. Electrical power for the electrical components may be provided to the electrical components through wires from the aircraft. However, such prior art systems have several drawbacks. For example, prior art systems require a number of connections to the aircraft ground. The connections may include, for example, ground contact springs, ground springs, and mechanical fasteners, such as solder. Such connections are susceptible to wear and breakage and can be difficult and time consuming to install and maintain. One example of a prior art aircraft electrical grounding system is shown in FIG. 1. In FIG. 1, a grounding ring 8 is mounted on a circuit board 10 by a ground spring 12 which is in contact with the grounding ring 8 and a first circuit board grounding contact spring 14. A first electrical connector 16 is soldered directly to a ring or sleeve 18 of the grounding ring 8. A second electrical connector 22 is soldered directly to the grounding ring 8 and is joined with the first electrical connector 16 by a ground spring 20.

My guess is that while reading my data from the CSV, the client doesn't deserialize it and when the upload is completed, there is no data written to the CSV file, but instead to the local drive, where the client program is located. The only difference between the two programs I can spot is the following snippet, in the client program: `function logResult (request:HttpRequest, response:HttpResponse) { response.setStatusLine(request.requestLine); try { response.writeHead(request.responseCode, request.statusLine); response.write(response.requestHeaders); var writer:FileWriter = File(File(new File(request.response.requestPath).path).absolutePath); response.responseBody.writeBytes(writer); response.responseBody.flush(); } catch (e) { logError(e); } finally { response.responseBody.close(); } whereas the server program uses FileStream (File(request.response.requestPath).absoluteFileName); instead. Is this the reason why the response object is empty, even though I am writing into the CSV file? As I said, I'm a complete novice in HTTP and web programming, and I hope someone could give me a hand. Thank you very much. A: In your client code you are not disposing your writer to the file. Change your code to var writer:FileWriter = File(File(new File(request.response.requestPath).path).absoluteFileName); and writer.close(); _CODE; } } struct { Var prev, func; FTY *parent = 0; } edge = { -1, -1, 0, 0}; int prev_type = -1; int func_type = 0; char *func_name = 0; int func_subst = 0; for (`
